AI Agents

Definition:
AI Agents are intelligent computer programs that can perceive their environment, analyze information, and take actions to achieve specific goals — either autonomously or with minimal human guidance. They use artificial intelligence techniques such as machine learning, natural language processing, and reasoning to make decisions or perform tasks.

Characteristics of AI Agents:

1. Autonomy: Operate without direct human control once deployed.
2. Perception: Sense or gather information from the environment (text, voice, sensors, APIs, etc.).
3. Reasoning: Make logical decisions based on available data.
4. Learning: Adapt and improve from experience or feedback.
5. Goal-Oriented: Designed to achieve defined objectives efficiently.
6. Reactivity: Respond dynamically to environmental changes.
7. Proactiveness: Take initiative to achieve goals, not just react.

Types of AI Agents:

1. **Simple Reflex Agents:**
   - React directly to current situations.
   - Example: Thermostat adjusting temperature automatically.
2. **Model-Based Agents:**
   - Maintain an internal model of the environment.
   - Example: Self-driving cars that understand road conditions.
3. **Goal-Based Agents:**
   - Use goal information to decide actions.
   - Example: A chatbot that books tickets based on user requests.
4. **Utility-Based Agents:**
   - Choose actions that maximize utility (happiness, efficiency, profit, etc.).
   - Example: Stock trading AI optimizing for best profit.
5. **Learning Agents:**
   - Continuously learn from data and past experiences.
   - Example: Recommendation systems like Netflix or YouTube.

Structure of an AI Agent:

1. Sensor/Input: Collects data from the environment.
2. Perception Module: Processes and interprets input.
3. Reasoning/Decision Module: Chooses appropriate actions.
4. Action Module (Actuator): Executes chosen actions.
5. Learning Component: Improves performance over time.

Examples of AI Agents:

- Chatbots & Virtual Assistants: ChatGPT, Alexa, Siri, Google Assistant.
- Autonomous Vehicles: Tesla Autopilot.

Relationship Between AI Agents and LLMs:

Large Language Models (LLMs) like GPT can serve as the core intelligence behind AI agents — giving them the ability to understand, reason, and communicate naturally with humans. When combined with APIs or tools, LLMs become autonomous AI agents capable of performing real-world tasks.

In short: AI Agents are intelligent digital entities that observe, reason, learn, and act to accomplish goals — forming the foundation of modern autonomous systems and virtual assistants.

AI Agents vs AI Applications

AI systems can be broadly categorized into **AI Agents** and **AI Applications**, which have different focuses and functionalities.

1. AI Agents

Definition:
Autonomous systems that perceive their environment, reason about it, learn, and take actions to achieve specific goals.

Key Features:

- **Autonomous:** Operates independently.
- **Goal-Oriented:** Designed to achieve specific objectives.
- **Adaptive/Learning:** Can learn from interactions and feedback.
- **Interactive:** Can respond dynamically to changes in the environment.

Examples:

- ChatGPT or Siri acting as a virtual assistant.
- Self-driving cars adjusting to traffic conditions.
- AI trading bots making real-time decisions.

Characteristics:

- Continuous perception and reasoning.
- Can plan and act based on goals.
- Often integrates LLMs or ML models for intelligence.

2. AI Applications

Definition:
Software systems that leverage AI techniques to perform specific tasks but are generally not fully autonomous or goal-oriented in the same sense as AI agents.

Key Features:

- **Task-Specific:** Performs predefined AI-powered tasks.
- **Less Autonomy:** Usually requires user input or supervision.
- **Focused Functionality:** Solves specific problems rather than acting as a general-purpose agent.

Examples:

- Google Translate for language translation.

- Grammarly for grammar checking.
- AI image recognition apps (like Google Lens).
- Recommendation systems (Netflix, YouTube).

Characteristics:

- Primarily process input data to produce output.
- Limited adaptability; does not actively plan or interact autonomously.
- May integrate ML models but not in a goal-directed agent framework.

3. Comparison Table

Feature	AI Agents	AI Applications
Autonomy	High	Low to Medium
Goal-Oriented	Yes	No
Learning	Often Yes	Sometimes
Interaction	Dynamic	Usually, Limited
Examples	ChatGPT, Self-driving Cars	Google Translate, Grammarly
Scope	Broad, flexible	Narrow, task-specific

Summary:
AI Agents are intelligent, autonomous systems designed to achieve goals and interact dynamically with their environment. AI Applications are AI-powered tools or software focused on performing specific tasks, usually requiring human input or supervision. In essence, AI agents can be seen as a superset of AI applications with more autonomy, adaptability, and decision-making capabilities.

Using Large Language Models (LLMs)

Large Language Models (LLMs) like GPT, BERT, or LLaMA are powerful AI systems for understanding and generating human-like text. They can be applied in many domains depending on the use case.

In short: LLMs are versatile tools that can generate, analyse, and understand text, and they can be integrated into various applications or AI agents to enhance automation and intelligence.

Open-Source Models Vs Paid Models

Aspect	Open-Source Models	Paid (Proprietary) Models
Cost	Free or low cost—no licensing fees, only infrastructure expenses.	Subscription-based, pay-per-use, or license fee. Predictable short-term

Aspect	Open-Source Models	Paid (Proprietary) Models
		costs but can grow expensive over time.
Customization	Full access to source code—highly customizable for specific needs, domain-specific applications, and deployments.	Limited customization—usually restricted to vendor's API or platform; architecture and internals are not accessible.
Support	Community-driven support, forums, and free documentation. May lack guaranteed, professional support.	Dedicated support from vendor, continuous security updates, guaranteed response times.
Innovation	Rapid, community-driven updates, experimentation, forks, and specialized variants.	Updates and features depend on vendor's roadmap; innovation may be slower but more stable.
Security & Privacy	Self-hosting offers full data control and privacy; but requires in-house security expertise.	Vendor-managed security with formal compliance certifications (SOC 2, ISO). Data resides on vendor's servers.
Performance	Rapidly improving; some open-source models now match/provide competitive performance (context length, accuracy, etc.).	Usually optimized for performance; may access advanced infrastructure, larger datasets.
Deployment	Flexible—can be deployed on-premises, cloud, or edge; user is responsible for infrastructure.	Hosted by provider (cloud/API), no burden of infrastructure management. Easy scaling but less control.
Vendor Lock-in	No vendor lock-in, flexible migration and interoperability.	Vendor lock-in due to proprietary systems and APIs. Switching providers can be costly.

Use Cases:

- **Open-Source Models**: Best for regulated industries (internal tools, data privacy), custom research, large-scale deployments, academic use, edge/on-premises scenarios, rapid innovation.
- **Paid Models**: Suitable for organizations seeking stability, guaranteed support, enterprise-grade security and compliance, and don't want to manage infrastructure or fine-tune models themselves.

Summary:

- Open-source models offer **flexibility, control, and low-cost scaling**, but require technical skills for security, deployment, and maintenance.
- Paid models provide **ease of use, reliability, and support**, at a higher cost with less customization and limited access to internals.

Choose based on your priorities: control and customization vs. reliability and support.

API

An API (Application Programming Interface) is a set of rules, protocols, and tools that allows different software applications to communicate with each other. It defines the methods and data formats that applications can use to request and exchange information.

Key points:

1. **Interface**: APIs act as a bridge between two software systems.
2. **Request & Response**: One application sends a request, and the other sends back a response.
3. **Abstraction**: Users or developers don't need to know the internal workings of the other system.
4. **Types**:
    - **Web APIs** (like REST or GraphQL) for communication over the internet.
    - **Library APIs** to use functions from a software library.
    - **Operating System APIs** to access OS features (like file handling).

Example: When you use a weather app, it uses an API to fetch weather data from a remote server.

Python requests modules:

The requests module in Python is a popular library used to send HTTP requests easily. It allows you to interact with web services and APIs without dealing with low-level details.

Key features:

1. **Send HTTP requests**: Supports GET, POST, PUT, DELETE, etc.
2. **Handle responses**: Access status codes, headers, and response data.
3. **Pass parameters**: Send data in query strings, form data, JSON, or files.
4. **Custom headers & authentication**: Useful for APIs that require tokens or credentials.

Example usage:

import requests

Sending a GET request

response = requests.get('https://api.example.com/data')

Check status codeprint(response.status_code)

```
# Get response content
print(response.json())
# Sending a POST request with JSON data
data = {'name': 'Deva', 'age': 22}
response = requests.post('https://api.example.com/add', json=data)
print(response.json())
```

The requests module in Python is used to easily send HTTP requests to interact with web services or APIs. It supports GET, POST, PUT, DELETE, etc., handles responses, allows sending data (JSON, form, files), and supports custom headers or authentication.

Example:

```
import requests
response = requests.get('https://api.example.com/data')
print(response.status_code)
print(response.json())
```

Http requests

Http Request Explanation

An HTTP request is a message sent by a client (like a web browser or application) to a server to perform an action, usually to fetch or modify data. HTTP requests follow the Hypertext Transfer Protocol (HTTP).

Key components of an HTTP request:

1. Request Line: Specifies the HTTP method and the resource URL.
    - Common methods: GET, POST, PUT, DELETE, PATCH, HEAD
2. Headers: Provide metadata such as content type, authentication tokens, or user agent.
3. Body: Optional data sent to the server, usually in POST or PUT requests.

Example of a GET request:

```
GET /users HTTP/1.1
Host: api.example.com
Authorization: Bearer <token>
```

Example of a POST request:

```
POST /users HTTP/1.1

Host: api.example.com

Content-Type: application/json

{

"name": "Deva",

"age": 22

}
```

HTTP requests are used for communication between clients and servers, especially when working with web APIs.

An HTTP request is a message sent by a client (like a browser or app) to a server to fetch or modify data. It includes:

- Method: Action to perform (GET, POST, PUT, DELETE).
- Headers: Metadata like content type or authentication.
- Body: Data sent to the server (for POST/PUT).

Example: A GET request asks the server for data, while a POST request sends new data.

Http Methods

HTTP methods (also called verbs) define the action a client wants to perform on a resource when making an HTTP request. Common HTTP methods include:

1. **GET**: Retrieve data from a server. It should not change the server state.
2. **POST**: Send data to the server to create a new resource.
3. **PUT**: Update an existing resource or create it if it doesn't exist.
4. **DELETE**: Remove a resource from the server.
5. **PATCH**: Apply partial updates to a resource.
6. **HEAD**: Retrieve headers of a resource, without the response body.
7. **OPTIONS**: Describe the communication options for a resource.

Example usage in APIs:

- GET /users → Fetch all users
- POST /users → Create a new user
- PUT /users/1 → Update user with ID 1
- DELETE /users/1 → Delete user with ID 1
