A.Cloud Computing

Cloud computing is the **delivery of computing services** — like **servers, storage, databases, networking, software, analytics, and more — over the internet ("the cloud")** instead of using your own local computer or data center.

In short:
➡️ You **rent** computing resources from a provider (like AWS, Azure, or Google Cloud)
➡️ You **pay only for what you use**, just like electricity or mobile data.

Example

Imagine you're building a website.
Instead of:

- Buying servers
- Setting them up manually
- Maintaining power, cooling, and backups

You can just **host it on AWS or Azure**, which automatically handles:

- Storage
- Traffic load balancing
- Security
- Backups

You just focus on your **code and business logic**.

B. **Main Cloud Models**

1. **IaaS (Infrastructure as a Service)** – you rent virtual machines, networks, storage (e.g., AWS EC2).
2. **PaaS (Platform as a Service)** – you deploy code without managing servers (e.g., Google App Engine).
3. **SaaS (Software as a Service)** – you use software online (e.g., Gmail, Google Drive, Zoom).

C. Cloud Deployment Models

1. Public Cloud

- **Owned & operated by third-party providers** like AWS, Azure, Google Cloud.
- Resources (servers, storage) are **shared** among multiple users ("tenants").
- You **pay only for what you use**.

Example: Hosting your app on AWS EC2 or storing files on Google Drive.

Pros:

- Low cost (no hardware needed)
- High scalability and reliability

Cons:

- Less control over data & infrastructure

2. Private Cloud

- Entire cloud infrastructure is **dedicated to one organization**.
- Can be **on-premises** (your own data center) or hosted by a third party.

Example: Banks or government organizations use private clouds for sensitive data.

Pros:

- High security and control
- Customizable infrastructure

Cons:

- Expensive to set up and maintain

3. Hybrid Cloud

- **Combination of public and private clouds**, working together.
- Organizations can keep **sensitive data** in a private cloud and **run other apps** in a public cloud.

Example: A hospital stores patient data privately but runs appointment booking on a public cloud.

Pros:

- Flexibility & scalability

- Better data control

Cons:

- Complex to manage

4. Community Cloud

- Shared by **several organizations** with common goals (e.g., government departments, universities).
- Managed internally or by a third party.

Pros:

- Cost shared among organizations
- Tailored to a specific community's needs

Cons:

- Less scalable than public cloud

Quick Recap Table

Model	Ownership	Example Use	Key Advantage
Public	Third-party provider	Web apps, startups	Low cost
Private	One organization	Banking, govt	High security
Hybrid	Mix of both	Enterprises	Flexibility
Community	Shared among orgs	Education, research	Collaboration

D. Five Characteristics of Cloud Computing

1. On-Demand Self-Service

You can access computing resources (like servers, storage, apps) **whenever you need**, without requiring human help from the provider.
Example: You can start a new virtual machine on AWS anytime via the console

2. Broad Network Access

Cloud services are available **over the internet** and can be accessed from **any device** (laptop, mobile, tablet).
Example: You can access Google Drive from a phone or PC.

3. Resource Pooling

The provider's resources are **pooled and shared** among multiple users using a **multi-tenant model**.
Each user's data and tasks are isolated but share the same physical infrastructure.
Example: Many users' apps run on the same AWS data center.

4. Rapid Elasticity

Cloud resources can be **quickly scaled up or down** depending on demand.
Example: An e-commerce site can add more servers during a sale and reduce them afterward.

5. Measured Service

Resource usage is **automatically monitored and billed** based on actual consumption (like pay-as-you-go).
Example: You pay AWS only for the amount of compute hours or storage used.

Quick Summary Table

Characteristic	Meaning	Example
On-Demand Self-Service	User can access resources anytime	Launching AWS EC2 instance
Broad Network Access	Accessible via internet	Using Gmail or Google Docs
Resource Pooling	Shared resources among users	AWS data center
Rapid Elasticity	Scalable resources	Auto-scaling web servers
Measured Service	Pay for what you use	Billing per hour on AWS

E. Six Advantages of Cloud Computing

1. Cost Efficiency

- No need to buy and maintain expensive hardware or software.
- You **pay only for what you use** (Pay-as-you-go model).
  Example: A startup can launch an app on AWS without buying servers.

2. Scalability and Flexibility

- Easily **scale resources up or down** based on demand.
- Perfect for businesses with **variable workloads**.
  Example: E-commerce sites scale up servers during festive sales.

3. High Availability and Reliability

- Cloud providers offer **redundant systems** and **automatic backups**.
- Ensures **minimal downtime** and quick recovery.
  Example: Google Cloud guarantees 99.99% uptime.

4. Accessibility and Mobility

- Access your data and apps from **anywhere, anytime**, using the internet.
  Example: You can edit a Google Docs file on your phone or laptop.

5. Automatic Updates

- The cloud provider handles all **software, security, and hardware updates** automatically.
  Example: Microsoft Azure automatically updates its services without downtime.

6. Enhanced Security

- Leading providers use **advanced encryption, firewalls, and identity management** to protect data.
  Example: AWS Identity and Access Management (IAM) controls access permissions.

Quick Recap Table

G. Types of Cloud Computing (Service Models)

Cloud computing services are mainly divided into **three major types**, also called **service models — IaaS, PaaS, and SaaS**.
You can remember them using the acronym **"IPS" → Infrastructure, Platform, Software**.

1. IaaS (Infrastructure as a Service)

- Provides **virtualized computing resources** over the internet.

- You rent servers, storage, and networks from a provider.
- You manage the **OS, applications, and data**, while the provider manages the **hardware**.

Examples:

- AWS EC2 (virtual servers)
- Google Compute Engine
- Microsoft Azure VM

Use Case:
Hosting websites, storage, and backup solutions.

2. PaaS (Platform as a Service)

- Provides a **platform** to develop, test, and deploy applications.
- You focus on your **code and logic**, while the provider manages the **infrastructure and runtime environment**.

Examples:

- Google App Engine
- Microsoft Azure App Service
- AWS Elastic Beanstalk

Use Case:
Building and deploying web or mobile apps without managing servers.

3. SaaS (Software as a Service)

- Delivers **ready-to-use applications** over the internet.
- You just use the software — no installation, maintenance, or updates needed.

Examples:

- Gmail
- Google Docs
- Zoom
- Salesforce

Use Case:
Email, collaboration tools, CRM systems, online storage.

Quick Comparison Table

Feature	IaaS	PaaS	SaaS
You Manage	OS, apps, data	Apps & data	Only usage
Provider Manages	Hardware	Hardware + OS	Everything
Example	AWS EC2	Google App Engine	Gmail
Users	Sysadmins, IT pros	Developers	End users

Analogy (Easy to Remember):

Imagine a **pizza** 🍕 :

- **IaaS:** You buy ingredients and cook at home.

I.AWS Global Infrastructure

AWS has a massive worldwide network of **data centers** designed for **high availability, low latency, and global reach**.
It is built using the following components:

1. Regions

- A **geographic area** where AWS has multiple data centers.

- Each Region is isolated from others for **fault tolerance** and **data sovereignty**.
- Example:
    - **ap-south-1 (Mumbai)**
    - **us-east-1 (N. Virginia)**
    - **eu-west-1 (Ireland)**

As of now: AWS has **30+ Regions** globally.

2. Availability Zones (AZs)

- Each Region contains **multiple isolated data centers**, called AZs.
- AZs are physically separate, each with its own power, cooling, and network.
- They are connected with **high-speed, low-latency** links.

Example:

- Mumbai Region has **3 AZs**:
    - ap-south-1a
    - ap-south-1b
    - ap-south-1c

Purpose:

- High availability
- Fault tolerance
- Redundancy

If one AZ fails, others run your applications without downtime.

3. Edge Locations

- These are **content delivery endpoints** of AWS — used mainly by **Amazon CloudFront (AWS CDN)**.
- They deliver content to users **with low latency** by caching data closer to the user.

Example uses:

- Faster video streaming
- Quick website loading
- Real-time content delivery

AWS has **500+ Edge Locations** worldwide.

4. Local Zones

- Special extension of Regions placed **near large population centers**.
- Provide **very low latency** for applications like gaming, video editing, and AR/VR.

Example:

- Los Angeles Local Zone
- Chennai Local Zone

5. Wavelength Zones

- AWS infrastructure embedded inside **telecom provider networks** (like Airtel/Verizon).
- Used for **ultra-low latency 5G applications**.

Example apps:

- Autonomous vehicles
- Smart factories
- Real-time video analytics
